## ABSTRACT OF DISCLOSURE

Light emitted from a taking lens 20 ontoro a first birefringent plate la to be spatially divided along a first direction extending perpondicular to the direction in which the light advances to achieve two separate rays £10 and £20. The vibrational planes of the two light fluxed L10 and L20 emitted from the first birefringent plate la are converted to a circularly polarized light by a phase place ic. The two light fluxes L10' and L20' emitted from the phase plate 10 lc are each spatially divided into two by a second birefringent plate 1d along a second direction extending perpendicular to the first direction to achieve four separate rays 111, 112, 121 and 122, to be guided to an imaging plane 15a of an imaging device 15. At least either the first birefringent plate or the second birefringent 15 place is constituted of lithium niobate, rutilo, Chilada nitrate, or the like.
